

Parking lot USB exercise

Contents	• The USB drive contains both personal and work-related files, including family photos, pet pictures, employee schedules, a new hire letter, and budget documents. • These files may contain personally identifiable information (PII) and sensitive business information. • Storing personal and work files together increases the risk of data exposure if the USB drive is lost or stolen.
Attacker mindset	• An attacker could use the personal and work information on the USB drive to launch phishing or social engineering attacks against Jorge, his family, or hospital employees. • Documents containing schedules, budgets, or employee information could also help an attacker gain unauthorized access to hospital systems or plan targeted attacks.
Risk analysis	• A malicious USB drive could contain malware, ransomware, or spyware that automatically infects a computer when connected. • Organizations can reduce this risk by training employees not to use unknown USB devices, disabling USB autorun, and scanning removable media in an isolated virtual environment before accessing it. • Keeping personal and work files separate, using endpoint protection software, and enforcing security policies also help protect sensitive information and reduce the impact of USB baiting attacks.
